# Chapter 1

## Introduction

In an increasingly connected world, cloud computing and the Internet of Things (IoT) are revolutionising many fields, including environmental monitoring. This technological development offers unprecedented possibilities for managing and analysing air quality, a major public health issue. This report, drawn up as part of my Master's degree in Cloud and Embedded Systems Science and Technology (CSTE), focuses on the use of these technologies to collect, process and distribute environmental data.

The main aim of this assignment is to store and make accessible the latest air quality data, captured by a network of small environmental IoT sensors. The project aims to provide a reliable platform for real-time consultation of environmental data, a crucial tool for researchers, decision-makers and the general public.

We face a number of technical challenges in achieving this objective. Firstly, managing the large quantities of data generated by IoT sensors requires a robust and adaptable cloud infrastructure. Secondly, calculating the Air Quality Index (AQI) from this data in real time requires considerable processing power and accuracy. Finally, the need to keep the system adaptable and responsive to varying workloads presents an additional challenge.

To address these challenges, our approach is to use a database located in the cloud, specifically designed to manage and process large volumes of IoT data. This database will be regularly updated with new data, while allowing quick and easy access for end users. In addition, we will be implementing advanced algorithms for calculating the AQI, guaranteeing the accuracy and reliability of the information provided.

The importance of this system is not limited to environmental monitoring; it also has a significant impact on public health, urban planning and environmental awareness. By providing accurate and up-to-date data, we contribute to a better understanding and management of air quality.

In conclusion, this report will detail our methodology, the architecture of the system, the challenges encountered and the solutions adopted. We will also discuss the implications of our work, not only in technical terms but also in terms of its practical applications and impact on different stakeholders.

# Chapter 2

## Methodologies

### 2.1 Data Collecting, Processing & Storing

#### 2.1.1 Overview of the Pipeline Architecture

The initial pipeline in this project consists of three primary components: **Data Collecting**, **Data Processing**, and **Data Storing**.

During the **Data Collecting** phase, the most recent version of the dataset is acquired from its source. This is followed by the **Data Processing** phase, where the data is formatted, and the Air Quality Index (AQI) is calculated for each particulate matter sensor. Lastly, in the **Data Storing** phase, the data from each sensor is methodically stored in a time-series database.

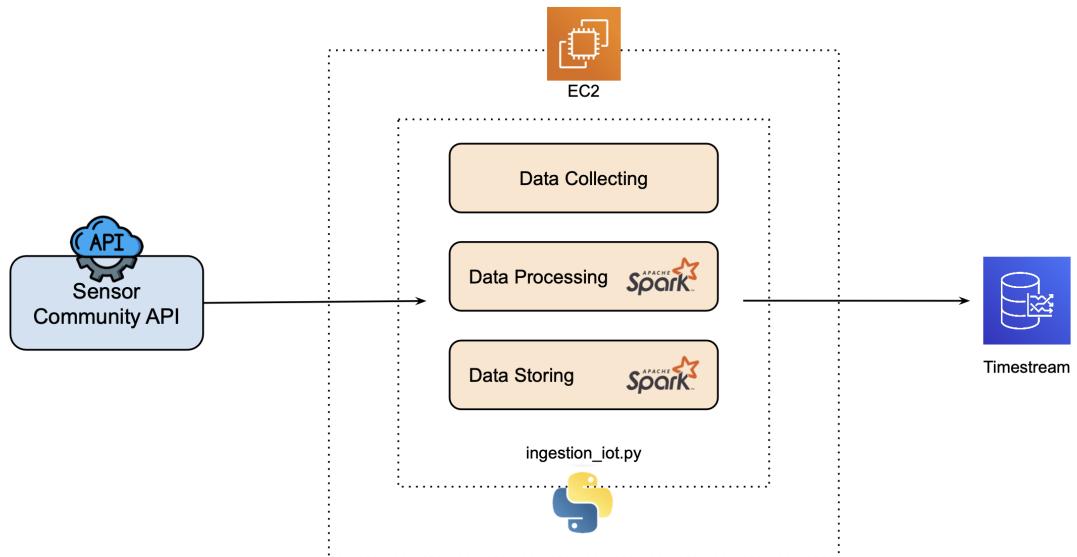

Figure 2.1: Data Collecting, Processing & Storing Pipeline Diagram

## 2.1.2 Data Collecting

### 2.1.2.1 Data Source

The Sensor Community network is a global, contributor-driven initiative that collects open environmental data through a vast network of sensors. These sensors, deployed in over 70 countries, collect real-time data on air quality, temperature, humidity and pressure. On average, the sensors send new data every 145 seconds (1). The Sensor Community network offers two main API endpoints for accessing their environmental data:

1. **5-Minute Averaged Data API:** This API provides data averaged over the last 5 minutes for each sensor. This is useful for near real-time analysis or immediate air quality assessments, particularly in test or active monitoring contexts.
2. **24 Hour Averaged Data API:** This API provides data averaged over the last 24 hours for each sensor. It is particularly suited to analysing daily trends and understanding environmental changes over a longer period.

### 2.1.2.2 Ingestion Script

The data acquisition process in this project involved leveraging both APIs from the Sensor Community. To facilitate this, the Python `requests` library was employed, enabling efficient data retrieval. Once collected, the data was temporarily stored in a local cache, formatted as a Spark DataFrame for optimized handling and processing. This operation, executed by the `fetch_sensors_data` function, is located within the `collecting.py` script (see Appendix B.B for detailed code). Notably, this function is programmed to run at a consistent interval of every 10 seconds, ensuring a steady and up-to-date flow of data from the sensors. This systematic approach not only streamlines the data collection process but also enhances the reliability and timeliness of the gathered information.

## 2.1.3 Data Processing

### 2.1.3.1 Processing Script

Once the data has been ingested, the `computeAQI` function is called to compute the Air Quality Index (AQI) values using user-defined functions (UDFs) that transform measured PM2.5 and PM10 concentrations into the corresponding AQI values, based on the thresholds as defined in Table 2.1. This operation, located within the `processing.py` script (see Appendix B.C for detailed code), utilises UDFs applied to a Spark DataFrame, a distributed collection of data organised into named columns, which facilitates data processing operations. The `explode` operation on the DataFrame transforms the sensor data values into individual rows, enabling the UDFs to be applied to each concentration measurement. The process is optimised by caching the DataFrame, thereby reducing processing time by minimising read and write operations to disk.

This procedure uses Apache Spark, a distributed data processing system, to calculate the AQI from data collected in real time by sensors. Spark's distributed approach is especially adept at managing the large volumes of data generated by sensors, enabling the AQI to be calculated quickly and efficiently.

Finally, the AQI is calculated by grouping the data by sensor ID and timestamp, followed by aggregation to determine the maximum AQI value between PM2.5 and PM10 particles. This ensures that the AQI reflects the highest concentration of pollutants, which is essential for an accurate assessment of exposure to air pollutants. This distributed calculation, performed in parallel across multiple processing nodes, illustrates the power of Spark in processing environmental IoT data, providing up-to-date and accurate air quality information that is essential for public health decision-making.

Table 2.1: UK air quality index, “Review of the UK Air Quality Index”, 2011

<b>Range</b>	<b>Air Quality Index</b>	<b>PM<sub>2.5</sub> Particles, 24 hour mean (<math>\mu\text{g}/\text{m}^3</math>)</b>	<b>PM<sub>10</sub> Particles, 24 hour mean (<math>\mu\text{g}/\text{m}^3</math>)</b>
Low	1	0-11	0-16
	2	12-23	17-33
	3	24-35	34-50
Medium	4	36-41	51-58
	5	42-47	59-66
	6	48-53	67-75
High	7	54-58	76-83
	8	59-64	84-91
	9	65-70	92-100
Very High	10	>70	>100

## 2.1.4 Data Storing

### 2.1.4.1 Database Choice

The difficulty with this project lies in the efficient management of data storage. Each sensor can measure a variety of data, making the structure of a single relational database too complex and inefficient. This complexity increases as the volume of data increases, requiring the creation of multiple linked tables. This structural challenge poses a performance problem, particularly when it comes to processing and analysing large quantities of data in real time, a crucial aspect for applications such as air quality or environmental monitoring.

Faced with these challenges, time series databases (TSDBs) are emerging as an optimal solution. Unlike traditional relational databases, TSDBs are specifically designed to manage time-series data, such as that from IoT sensors. They offer better performance in tracking, monitoring and aggregating data over time. In addition, TSDBs such as Amazon Timestream stand out for their ability to ingest data quickly and process large volumes efficiently, while ensuring regular updates and in-depth analysis, essential aspects for applications such as Air Quality Index analysis.

Amazon Timestream is a good choice for this project. As a cloud-native time-series database, it offers superior time-series management capabilities tailored to IoT sensor data. What sets Amazon Timestream apart is the speed with which it ingests data and its efficiency in processing large volumes of data, enabling regular updates and in-depth analysis. Its ability to adapt to changing workloads ensures consistent performance, a

major advantage for real-time data management. What's more, its advanced security features meet strict standards of confidentiality and data sovereignty, an essential

### 2.1.4.2 Storing Script

The data storing process represents the final phase in the IoT data collecting and processing pipeline. Once the Air Quality Index (AQI) has been calculated, the data must be stored efficiently and securely to allow subsequent analysis and real-time consultation. The `storing.py` script (see Appendix [refappendix:storing](#) for detailed code) is designed to interact with the Amazon Timestream database.

The `keepOnlyUpdatedRows` function is responsible for checking what data is already in Timestream and keeping only the newly updated values. This process begins by querying Timestream to retrieve the latest data timestamp for each sensor using the ‘`boto3`’ client. The data is then filtered to exclude records that do not reflect new measurements, optimising storage space and database performance.

Once this filtering is complete, the `writeToTimestream` function takes over. It transforms each partition of the Spark DataFrame into a series of structured records, containing the dimensions and measurements corresponding to each sensor. These records are then written to Timestream in batches. The process is carefully managed to ensure that records are written atomically and consistently, with robust exception handling to deal with any rejected records.

In conclusion, the integration of Spark with Amazon Timestream offers a powerful solution for storing environmental sensor data. Spark’s ability to process and filter data in a distributed manner aligns perfectly with Timestream’s high availability and auto-scaling capabilities, ensuring a resilient, high-performance data infrastructure. This arrangement enables reliable data storage and rapid retrieval, which are essential for continuous monitoring of air quality and rapid responses to environmental issues.

### 2.1.5 Pipeline Implementation on AWS

Setting up an IoT data processing pipeline on Amazon Web Services (AWS) involves several key steps, from configuring the EC2 instance to running and managing the pipeline. The process is described below:

1. **EC2 Instance Configuration:** An EC2 t4g.small instance has been configured to host the data pipeline. A t4g.small instance was chosen for its balance between performance and energy efficiency. These instances, based on ARM architecture, are ideal for light to moderate workloads, which correspond to the requirements of continuous data processing. In addition, Apache Spark has been installed on this instance to process the data collected. Spark was chosen for its ability to process data in memory and in parallel, optimising performance for data processing workloads.
2. **Setting Up Automated Services:** Two systemd services were then set up to automate the essential tasks: The `get_iam_credentials.service` (see Appendix B.E.2.1) executes `get_iam_credentials.sh` (see Appendix B.E.1). This script retrieves the instance's IAM credentials, enabling secure integration with other AWS services. The `spark_python_job.service` (see Appendix B.E.2.2) launches `start_spark_job.sh` (see Appendix B.E.1), which starts the main data processing script (see Appendix B.A). This script orchestrates the collection, processing (AQI calculation) and storage of IoT sensor data. These services are activated each time the instance is started.

## 2.2 Data Distributing

### 2.2.1 Overview of the Pipeline Architecture

The second pipeline in this project is the one responsible for distributing the data collected. Here is a brief overview of the pipeline architecture:

#### 1. Internet Gateway:

Users initiate their interaction with the system through the secure Internet Gateway. Access to the Grafana dashboards is facilitated through a dedicated URL, which can be visited at: Air Quality Monitoring Dashboard.

#### 2. Load Balancer:

The Load Balancer evenly distributes incoming traffic to the EC2 instances, ensuring balanced workload distribution and optimal resource utilization.

#### 3. Grafana Dashboard Access:

A Grafana dashboard, hosted on one of the Load Balancers, presents the ingested data stored in the Timestream database, providing real-time visualization of the air quality metrics.

#### 4. CloudWatch Monitoring:

AWS CloudWatch continuously monitors the total CPU utilization across all EC2 instances within the Auto Scaling Group. Depending on the aggregated CPU usage, CloudWatch dynamically upscales or downscales the resources to maintain system efficiency and cost-effectiveness.

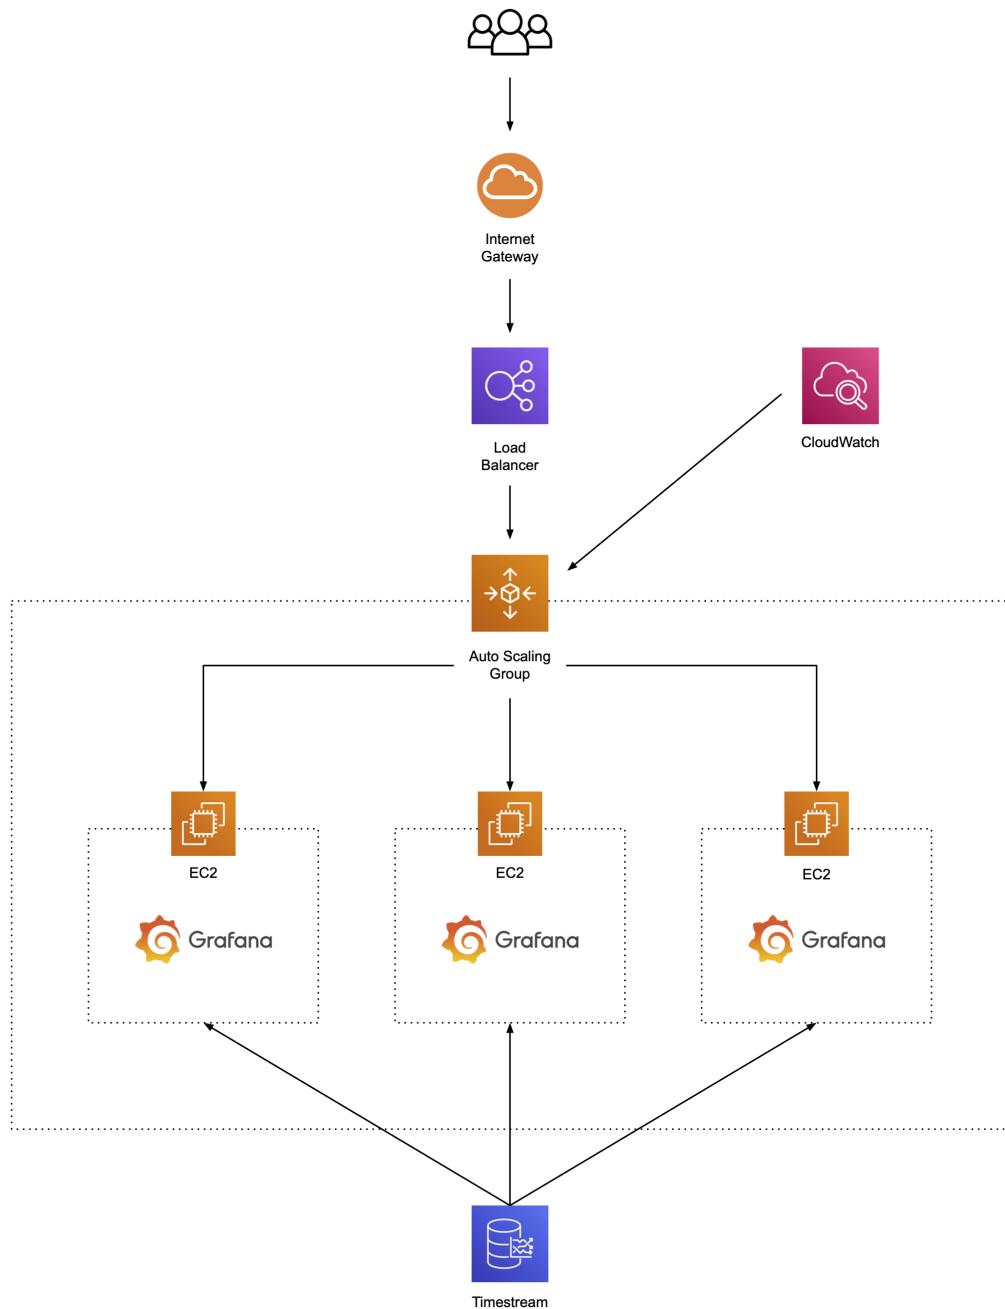

Figure 2.2: Data Distributing Pipeline Diagram

### 2.2.2 Auto Scaling Group Configuration

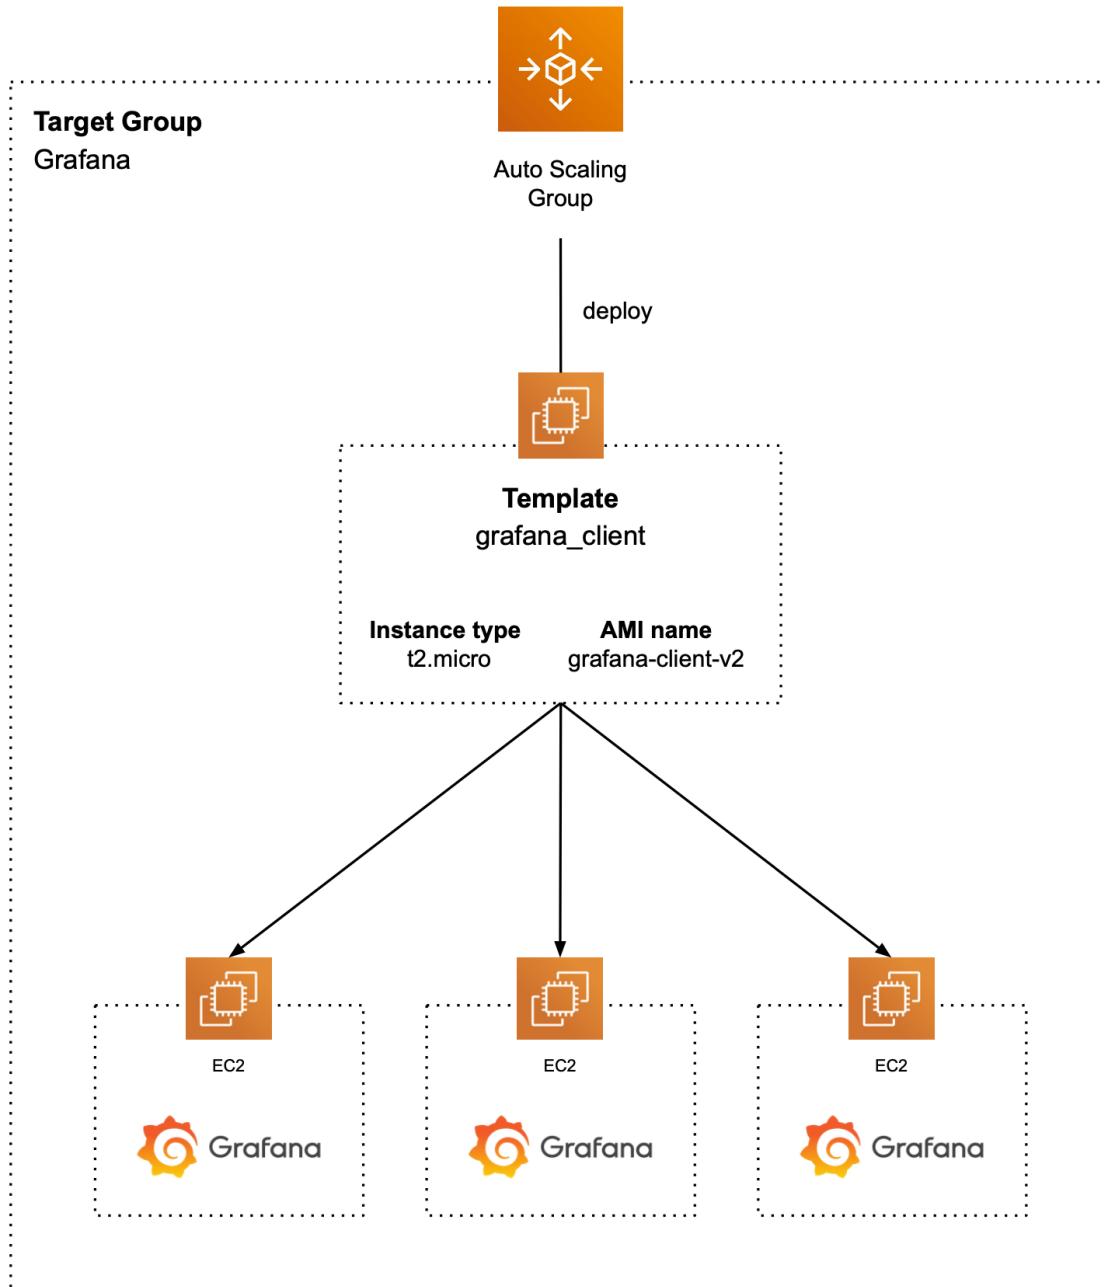

Figure 2.3: Auto Scaling Group Pipeline Diagram

### 2.2.2.1 AMI Configuration

An Amazon Machine Image (AMI) is a template that contains the software configuration (operating system, application server, and applications) required to launch an EC2 instance. A custom AMI using the Amazon Linux 2 operating system was created to host the Grafana server.

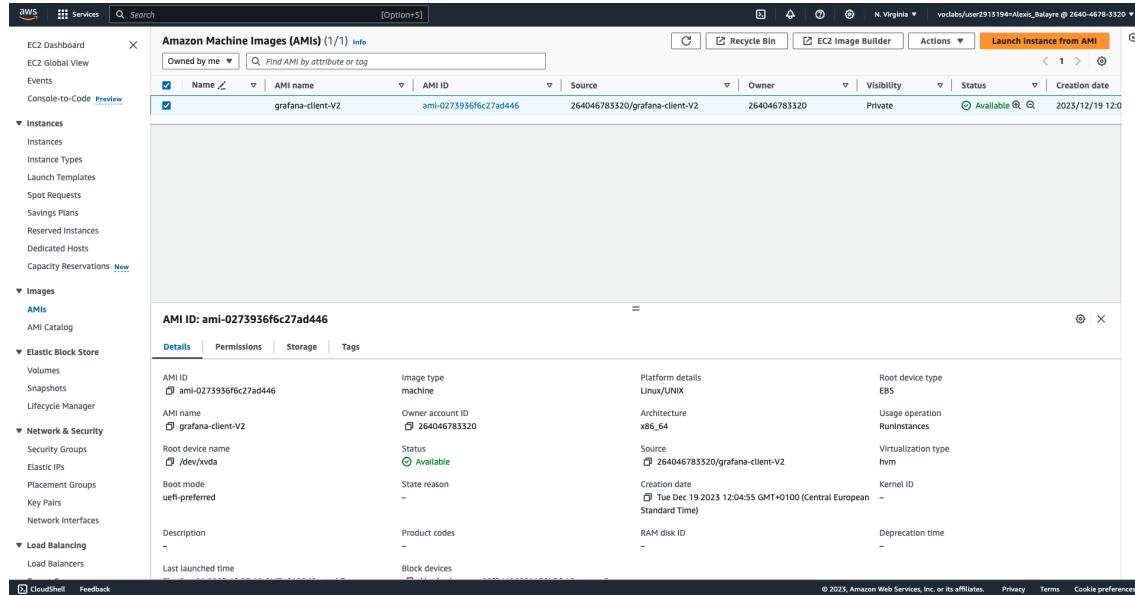

Figure 2.4: AMI Settings Screenshot

### 2.2.2.2 Launch Template Configuration

A launch template was defined to deploy the EC2 instances in the Auto Scaling Group using the custom AMI. The launch template also defines the instance type, security group, key pair, and user data.

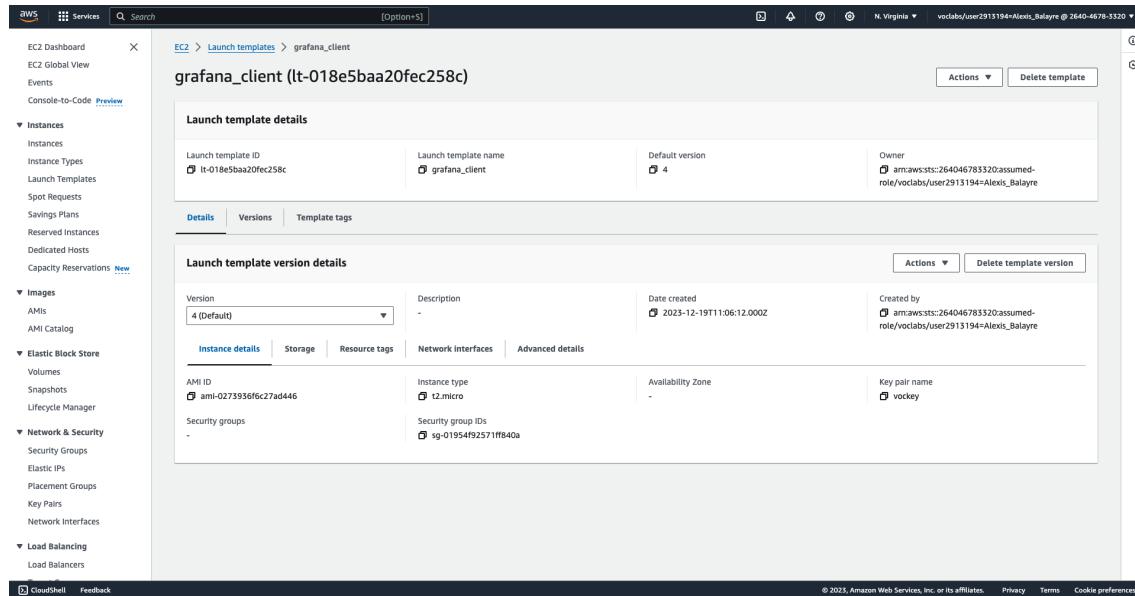

Figure 2.5: Launch Template Settings Screenshot

### 2.2.2.3 Auto Scaling Group Configuration

An Auto Scaling Group was created to manage the EC2 instances of the Distributing Data Pipeline. The Auto Scaling Group is configured to use the launch template and to scale between 1 and 5 instances, depending on the CPU utilization of the instances. The Auto Scaling Group also defines the target group and load balancer to use for distributing traffic between the instances.

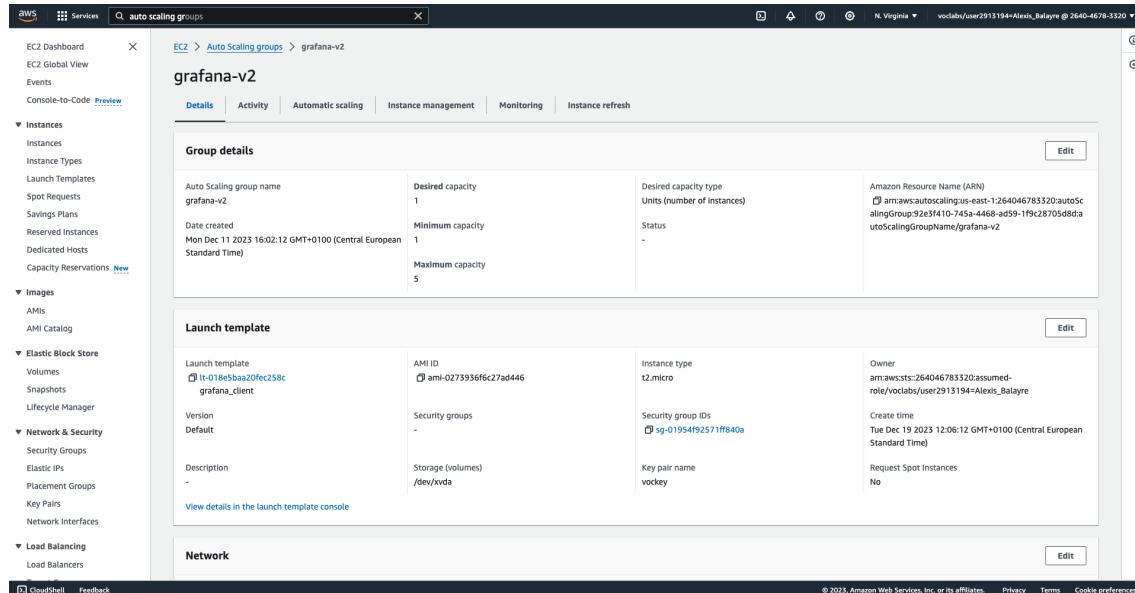

Figure 2.6: Auto Scaling Group Settings Screenshot

The Auto Scaling Group is configured to use the following scaling policy:

- Scale-out Policy:** The scale-out policy is triggered when the average CPU utilization of the instances is greater than 60% for 3 minutes. The scale-out policy adds 1 instance to the Auto Scaling Group.
- Scale-in Policy:** The scale-in policy is triggered when the average CPU utilization of the instances is less than 42% for 15 minutes. The scale-in policy removes 1 instance from the Auto Scaling Group.
- Coldown Period:** The cooldown period is set to 60 seconds to prevent the Auto Scaling Group from scaling in or out too quickly.

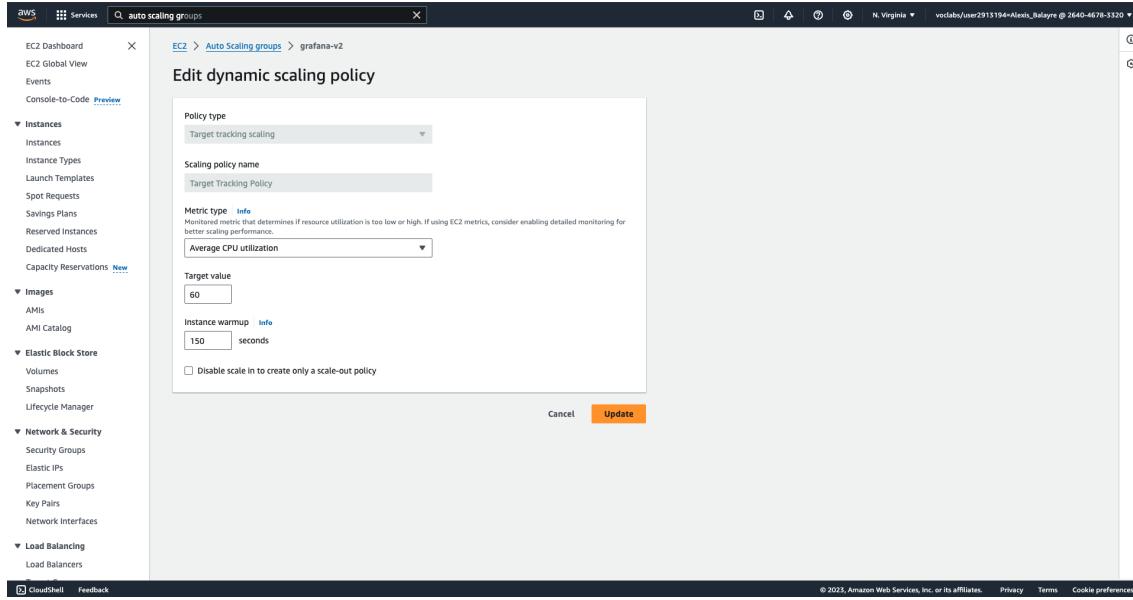

Figure 2.7: Scaling Policy Settings Screenshot

### 2.2.2.4 Target Group Configuration

A target group was created to distribute traffic between the EC2 instances of the Auto Scaling Group.

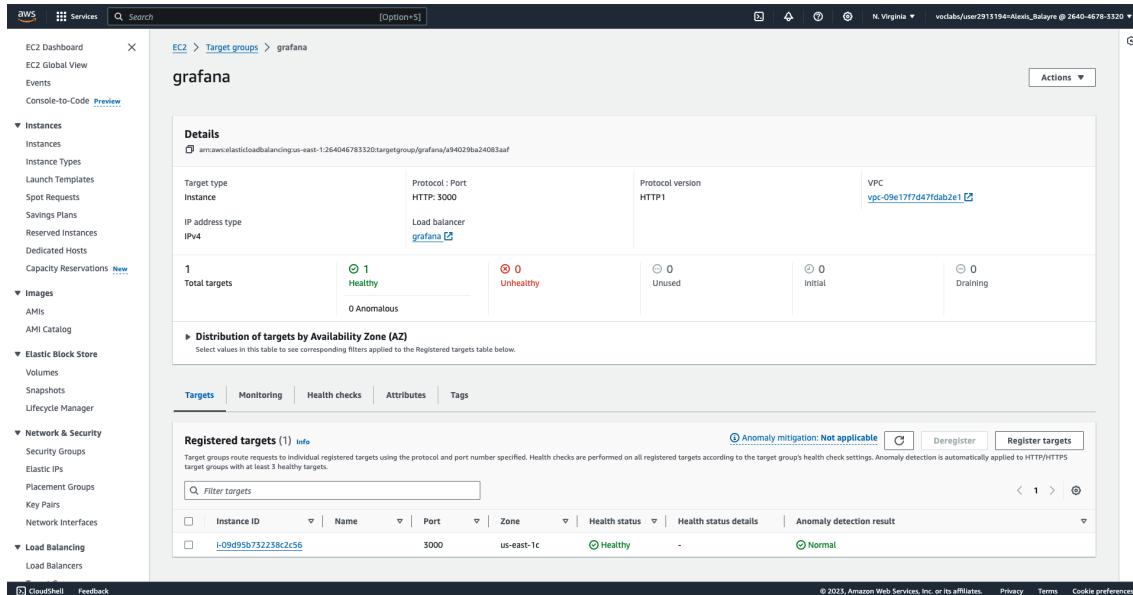

Figure 2.8: Target Group Settings Screenshot

### 2.2.2.5 Load Balancer Configuration

A load balancer was created to distribute traffic between the EC2 instances of the Auto Scaling Group. The load balancer is configured to use the target group and to listen on port 80.

The screenshot shows the AWS Management Console interface for managing a Load Balancer named 'grafana'. The left sidebar contains navigation links for EC2 Dashboard, EC2 Global View, Events, Console-to-Code, Instances, Images, Network & Security, and Load Balancing. The main content area displays the 'Details' tab for the 'grafana' load balancer. Key configuration details include:

- Load balancer type:** Application
- Status:** Active
- VPC:** vpc-09e17f7d47fdab2e1
- IP address type:** IPv4
- Hosted zone:** Z35SX0DTRQ7X7K
- Availability Zones:** us-east-1d (use1-az2), us-east-1a (use1-az4), us-east-1e (use1-az3), us-east-1c (use1-az1), us-east-1b (use1-az6), us-east-1f (use1-az5)
- Date created:** December 11, 2023, 16:46 (UTC+01:00)
- Load balancer ARN:** arn:aws:elasticloadbalancing:us-east-1:264046793520:loadbalancer/app/grafana/e8797fc823aa9503
- DNS name:** grafana-1777174802.us-east-1.elb.amazonaws.com (A Record)

Below the 'Details' tab, the 'Listeners and rules' tab is selected, showing one listener rule for port 80:

Protocol:Port	Default action	Rules	ARN	Security policy	Default SSL/TLS certificate	mTLS
HTTP:80	Forward to target group grafana (1 (100%)) Group-level stickiness: Off	1 rule	Not applicable	Not applicable	Not applicable	No

Figure 2.9: Load Balancer Settings Screenshot

## 2.3 Pipeline of the Project

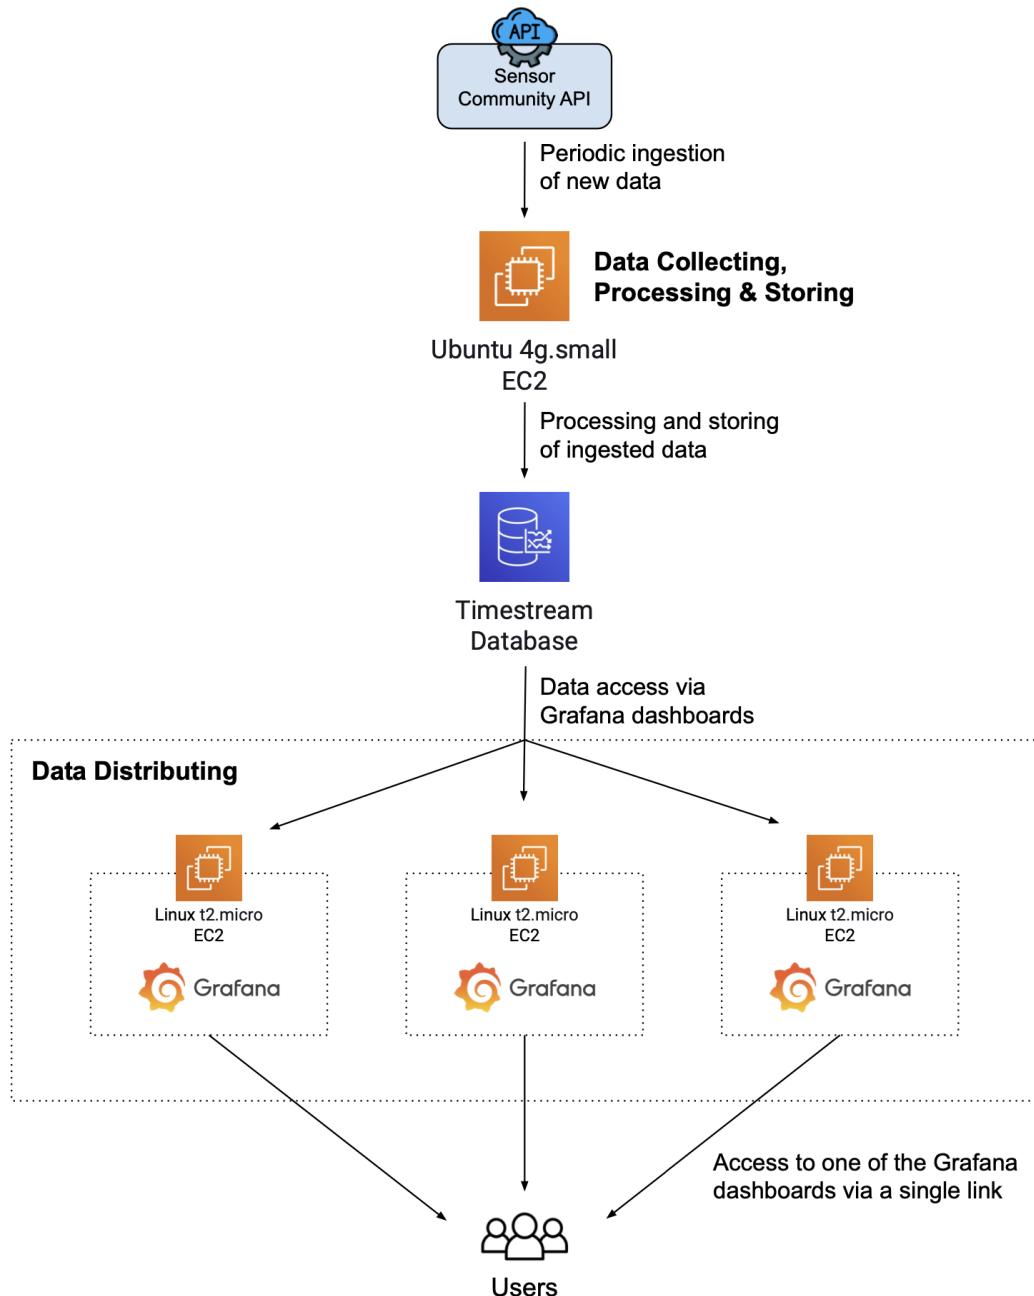

Figure 2.10: Data Distributing Pipeline Diagram

# Chapter 3

## Results & Discussion

### 3.1 Results

#### 3.1.1 Accessing the Data - Grafana Dashboard

The Grafana dashboard, a vital tool in air quality monitoring, is accessible at the following URL: Air Quality Monitoring Dashboard.

The Grafana dashboard provides an interactive interface enabling users to analyse air quality data. Users can customise the time interval, measurement value and location ID. The dashboard consists of five main panels, each providing unique information:::

1. **Measure Value Evolution:** This panel shows the evolution of the selected measure value in the selected location over the selected time range.
2. **Max AQI:** This panel shows the maximum AQI value in the selected location over the selected time range.
3. **Mean AQI:** This panel shows the mean AQI value in the selected location over the selected time range.
4. **AQI Map:** This panel shows the AQI value of each location on a map.
5. **IoT Data:** This panel shows all the data collected by the IoT sensors related to the selected

## Chapter 3. Results & Discussion

### 3.1. Results

Figure 3.5: Grafana Dashboard IoT Data Panel - Measure Value Choice

Figure 3.6: Grafana Dashboard IoT Data Panel - Apply a Filter

The screenshot shows a Grafana dashboard titled "Air Quality Monitoring". On the left, there is a table titled "IoT Data" with columns: measure\_name (aqi), location\_ID (64294), sensor\_id, location\_id, latitude, longitude, and country. The data in the table consists of multiple rows of sensor readings. On the right, a modal window titled "Inspect: IoT Data" is open, showing the same data in a more detailed format. The modal has tabs for "Data", "Stats", "Meta data", and "JSON", with "Data" selected. It also includes "Data options" like "Formatted data" and "Download CSV" and "Download for Excel". The data in the modal is identical to the table on the left.

Figure 3.7: Grafana Dashboard IoT Data Panel - Export Values

### 3.1.2 Load Test

In order to test the scalability of the system, a load test was performed using the Artillery load testing framework. The test consisted in simulating an increasing number of customers consuming the grafana dashboards simultaneously, to demonstrate the elasticity of the solution developed. The results of the test are shown in Figure 3.8.

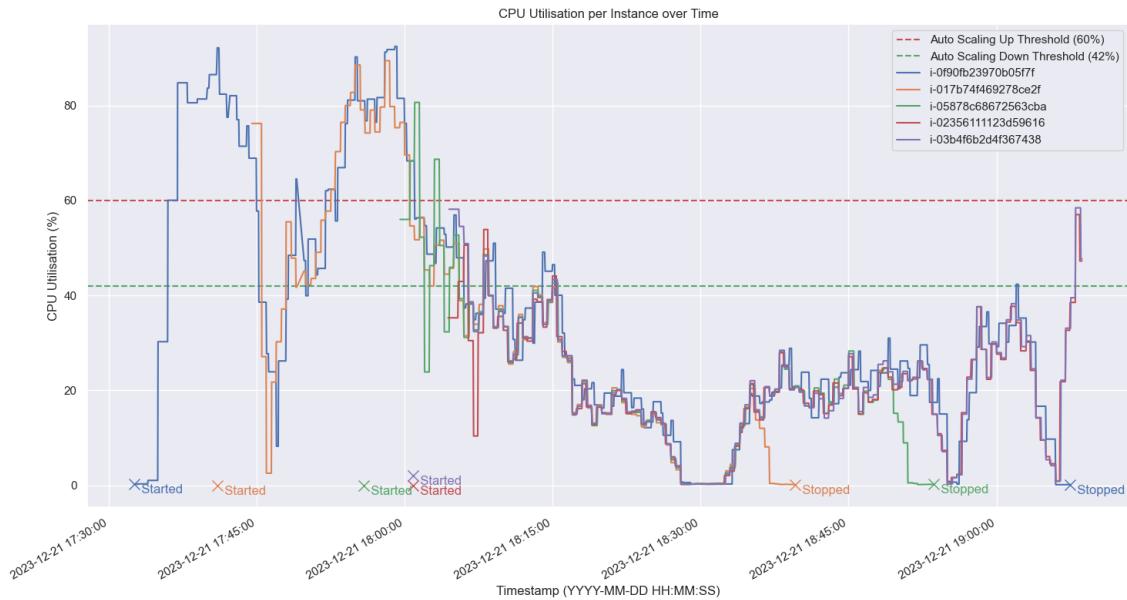

Figure 3.8: Load Test Result

## 3.2 Data Security and Sovereignty Considerations

Data security and sovereignty are critical in the management of environmental sensor data. Recent research trends in IoT security highlight the evolving landscape of threats and protections in this field (2).

### 3.2.1 Data Security

In the realm of IoT, ensuring data security involves advanced encryption, robust access control, and maintaining data integrity. The systematic mapping study by (**author?**) provides insights into current methodologies and research directions in IoT security, relevant to environmental sensor data.

### 3.2.2 Data Sovereignty

Data sovereignty is influenced by varying international legislations, such as GDPR, affecting data storage and cross-border data transfer. The study by (**author?**) underscores the importance of understanding these legal complexities in IoT environments.

### 3.2.3 Specific Fields for Further Examination

Areas needing heightened attention include personal data protection, sensitivity of environmental data, and metadata security, as indicated by recent IoT security research trends (2).

Adhering to the latest security trends and regulatory frameworks is vital for the ethical management of environmental sensor data. The evolving research in IoT security serves as a guide for future developments in this field (2).

# **Chapter 4**

## **Conclusion**

In conclusion, this study presents a significant advancement in air quality monitoring through IoT technologies, demonstrating the effectiveness of the Grafana dashboard in data visualization and analysis. The successful load test indicates the system's scalability, catering to simultaneous user access. Addressing data security and sovereignty, the project highlights the importance of robust data management practices in IoT environments. While acknowledging certain limitations, this research lays a foundation for future explorations in IoT security and data handling. Overall, it contributes valuable insights to the field of environmental monitoring and data security, underscoring the potential of IoT in addressing critical ecological issues.

### Appendix A.B Getting Started

To run the program, follow these steps:

1. Create a virtual environment using `python3 -m venv venv`.
2. Activate the virtual environment using `source venv/bin/activate`.
3. Install the required dependencies using `pip3 install -r requirements.txt`.
4. Run the program using `python3 main.py`.
5. Visualise the results using `visualisation.ipynb` (Jupyter Notebook).

## Appendix A.C Detailed Features of Functions

collecting.py

- `fetch_sensors_data(sparkSession)`: Function to ingest the latest data from the sensors and returns it as a Spark DataFrame.

processing.py

- `get_aqi_value_p25(value)`: Function for calculating the AQI value for PM2.5.
- `get_aqi_value_p10(value)`: Function for calculating the AQI value for PM10.
- `computeAQI(df)`: Function for calculating the AQI value for each particulate matter sensor and returning the DataFrame with the AQI column.

storing.py

- `keepOnlyUpdatedRows(database_name, table_name, df)`: Function for keeping only the rows that have been updated in the DataFrame.
- `_print_rejected_records_exceptions(err)`: Internal function for printing the rejected records exceptions.
- `write_records(database_name, table_name, client, records)`: Internal function for writing a batch of records to the Timestream database.
- `writeToTimestream(database_name, table_name, partitionned_df)`: Function for writing the DataFrame to the Timestream database.

## Appendix B.E Scripts & Services Source Codes

### B.E.1 Scripts

Script used by the `get_iam_credentials` service to retrieve the IAM credentials from the metadata server.

```
#!/bin/bash

# Get the authentication token from the EC2 metadata service
TOKEN=$(curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-
metadata-token-ttl-seconds: 21600" -s)

# Name of the IAM role to assume
ROLE_NAME="LabRole"

# Get temporary credentials using the IAM role
IAM_ROLE_CREDENTIALS=$(curl -H "X-aws-ec2-metadata-token: $TOKEN" -s http
://169.254.169.254/latest/meta-data/iam/security-credentials/$ROLE_NAME)

# Extract the credentials and session token
AWS_ACCESS_KEY_ID=$(echo $IAM_ROLE_CREDENTIALS | jq -r .AccessKeyId)
AWS_SECRET_ACCESS_KEY=$(echo $IAM_ROLE_CREDENTIALS | jq -r .SecretAccessKey)
AWS_SESSION_TOKEN=$(echo $IAM_ROLE_CREDENTIALS | jq -r .Token)
AWS_DEFAULT_REGION="us-east-1"

# Export the credentials and session token
export AWS_ACCESS_KEY_ID
export AWS_SECRET_ACCESS_KEY
export AWS_SESSION_TOKEN
export AWS_DEFAULT_REGION
```

Script used by the `spark_python_job` service to run the Python Spark job.

```
#!/bin/bash

# Run the spark job in the background and log output to output.log file
nohup python3 /home/ubuntu/iot_project/ingestion_iot.py >/home/ubuntu/iot_project/
output.log 2>&1 &
```

## B.E.2 Services

### B.E.2.1 Get IAM Credentials Service

Service used by the Ubuntu EC2 instance to retrieve the IAM credentials from the metadata server.

```
[Unit]
Description=Script to setup AWS cli thanks to the attached IAM Profile

[Service]
ExecStart=/usr/local/bin/get_iam_credentials.sh

[Install]
WantedBy=multi-user.target
```

### B.E.2.2 Spark Python Job Service

Service used by the Ubuntu EC2 instance to run the Python Spark job (Data Collecting, Processing and Storing).

```
[Unit]
Description=Script to run the ingestion python script

[Service]
ExecStart=/usr/local/bin/start_spark_job.sh

[Install]
WantedBy=multi-user.target
```

### B.E.2.3 Grafana Server Service

Service used by the Linux EC2 instances to run the Grafana server (Data Distributing).

```
[Unit]
Description=Grafana instance
Documentation=http://docs.grafana.org
Wants=network-online.target
After=network-online.target
After=postgresql.service mariadb.service mysqld.service influxdb.service

[Service]
EnvironmentFile=/etc/sysconfig/grafana-server
User=grafana
Group=grafana
Type=notify
Restart=on-failure
WorkingDirectory=/usr/share/grafana
RuntimeDirectory=grafana
RuntimeDirectoryMode=0750
ExecStart=/usr/share/grafana/bin/grafana server
    \
        --config=${CONF_FILE}
    \
        --pidfile=${PID_FILE_DIR}/grafana-server.pid
